EXISTENCE AND UNIFORM BOUNDEDNESS OF
OPTIMAL SOLUTIONS OF VARIATIONAL PROBLEMS

ALEXANDER J. ZASLAVSKI

ABSTRACT. Given an \( x_0 \in R^n \) we study the infinite horizon problem of minimizing the expression \( \int_0^T f(t, x(t), x'(t))dt \) as \( T \) grows to infinity where \( x : [0, \infty) \rightarrow R^n \) satisfies the initial condition \( x(0) = x_0 \). We analyse the existence and the properties of approximate solutions for every prescribed initial value \( x_0 \). We also establish that for every bounded set \( E \subset R^n \) the \( C([0,T]) \) norms of approximate solutions \( x : [0,T] \rightarrow R^n \) for the minimization problem on an interval \([0,T]\) with \( x(0), x(T) \in E \) are bounded by some constant which does not depend on \( T \).

INTRODUCTION

The study of variational and optimal control problems defined on infinite intervals has recently been a rapidly growing area of research. These problems arise in engineering (see Anderson and Moore [1], Artstein and Leizarowitz [2]), in models of economic growth (see Rockafellar [14], Zaslavski [20]), in infinite discrete models of solid-state physics related to dislocations in one-dimensional crystals which are under discussion in Aubry and Le Daeron [3], Zaslavski [16] and in the theory of thermodynamical equilibrium of materials (see Leizarowitz and Mizel [12], Coleman, Marcus and Mizel [7], Zaslavski [17, 18]).

We consider the infinite horizon problem of minimizing the expression

\[
\int_0^T f(t, x(t), x'(t))dt
\]

as \( T \) grows to infinity where a function \( x : [0, \infty) \rightarrow K \) is absolutely continuous (a.c.) and satisfies the initial condition \( x(0) = x_0, K \subset R^n \) is a...
closed convex set and \( f \) belongs to a complete metric space of functions to be described below.

The following notion known as the overtaking optimality criterion was introduced in the economics literature by Gale [8] and von Weizsacker [15] and has been used in control theory by Artstein and Leizarowitz [2], Brock and Haurie [5], Carlson [6] and Leizarowitz [11].

An a.c. function \( x : [0, \infty) \to K \) is called \((f)\)-overtaking optimal if for any a.c. function \( y : [0, \infty) \to K \) satisfying \( y(0) = x(0) \)

\[
\limsup_{T \to \infty} \int_0^T [f(t, x(t), x'(t)) - f(t, y(t), y'(t))] dt \leq 0.
\]

Usually it is difficult to establish the existence of overtaking optimal solutions, and actually, in general they may fail to exist. Most studies that are concerned with their existence assume convex integrands ([11], [5], [14]).

Another type of optimality criterion for infinite horizon problems (which is probably the weakest optimality concept) was introduced by Aubry and Le Daeron [3] in their study of the discrete Frenkel-Kontorova model related to dislocations in one-dimensional crystals. More recently this optimality criterion was used by Moser [13], Leizarowitz and Mizel [12] and Zaslavski [16]. A similar notion was introduced in Halkin [9] for his proof of the maximum principle.

Let \( I \) be either \([0, \infty)\) or \((-\infty, \infty)\). An a.c. function \( x : I \to K \) is called an \((f)\)-minimal solution if for each \( T_1 \in I, T_2 > T_1 \) and each a.c. function \( y : [T_1, T_2] \to K \) which satisfies \( y(T_i) = x(T_i), i = 1, 2 \) the following relation holds:

\[
\int_{T_1}^{T_2} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))] dt \leq 0.
\]

Clearly every \((f)\)-overtaking optimal function is an \((f)\)-minimal solution.

In the present paper we consider a functional space of integrands \( \mathcal{M} \) described in Section 1 and analyze existence and properties of \((f)\)-minimal solutions with \( f \in \mathcal{M} \). More exactly we will show that given \( f \in \mathcal{M} \) and \( z \in \mathbb{R}^n \) there exists a bounded \((f)\)-minimal solution \( Z : [0, \infty) \to \mathbb{R}^n \) satisfying \( Z(0) = z \) such that any other a.c. function \( Y : [0, \infty) \to \mathbb{R}^n \) is not “better” than \( Z \). We will also establish that given \( f \in \mathcal{M} \) and a bounded set \( E \subset \mathbb{R}^n \) the \( C([0, T]) \) norms of approximate solutions \( x : [0, T] \to \mathbb{R}^n \) for the minimization problem on an interval \([0, T]\) with \( x(0), x(T) \in E \) are bounded by some constant which depends only on \( f \) and \( E \). These results which are valid for any \( f \in \mathcal{M} \) have been applied in [19] to get more information about the existence of optimal solutions over an infinite horizon and about the structure of optimal solutions on finite intervals for a generic integrand \( f \in \mathcal{M} \).

The paper is organized as follows. In Section 1 we state our main theorems, Section 2 contains several preliminary results, in Section 3 we consider discrete-time control systems obtained by discretization of variational problems and in Section 4 we prove the main theorems.
1. Statements of main results

Let $K \subset \mathbb{R}^n$ be a closed convex set. Denote by $| \cdot |$ the Euclidean norm in $\mathbb{R}^n$ and denote by $\mathcal{M}$ the set of continuous functions $f : [0, \infty) \times K \times \mathbb{R}^n \to \mathbb{R}$ which satisfy the following assumptions:

(A) (i) for each $(t, x) \in [0, \infty) \times K$ the function $f(t, x, \cdot) : \mathbb{R}^n \to \mathbb{R}^1$ is convex;
(ii) the function $f$ is bounded on $[0, \infty) \times E$ for any bounded set $E \subset K \times \mathbb{R}^n$;
(iii) $f(t, x, u) \geq \sup \{\psi(|x|), \psi(|u|)|u|\} - a$ for each $(t, x, u) \in [0, \infty) \times K \times \mathbb{R}^n$ where $a > 0$ is a constant and $\psi : [0, \infty) \to [0, \infty)$ is an increasing function such that $\psi(t) \to \infty$ as $t \to \infty$ (here $a$ and $\psi$ are independent on $f$);
(iv) for each $M, \epsilon > 0$ there exist $\Gamma, \delta > 0$ such that

$$|f(t, x_1, u_1) - f(t, x_2, u_2)| \leq \epsilon \sup \{f(t, x_1, u_1), f(t, x_2, u_2)\}$$

for each $t \in [0, \infty)$, each $u_1, u_2 \in \mathbb{R}^n$ and each $x_1, x_2 \in K$ which satisfy

$$|x_i| \leq M, |u_i| \geq \Gamma, i = 1, 2, \sup \{|x_1 - x_2|, |u_1 - u_2|\} \leq \delta;$$

(v) for each $M, \epsilon > 0$ there exist $\delta > 0$ such that

$$|f(t, x_1, u_1) - f(t, x_2, u_2)| \leq \epsilon$$

for each $t \in [0, \infty)$, each $u_1, u_2 \in \mathbb{R}^n$ and each $x_1, x_2 \in K$ which satisfy

$$|x_i|, |u_i| \leq M, i = 1, 2, \sup \{|x_1 - x_2|, |u_1 - u_2|\} \leq \delta.$$

When $K = \mathbb{R}^n$ it is an elementary exercise to show that an integrand $f = f(t, x, u) \in C^1([0, \infty) \times \mathbb{R}^n \times \mathbb{R}^n)$ belongs to $\mathcal{M}$ if $f$ satisfies assumptions (Ai), (Aiii) with a constant $a > 0$ and a function $\psi : [0, \infty) \to [0, \infty)$,

$$\sup \{|f(t, 0, 0)| : t \in [0, \infty)\} < \infty$$

and there exists an increasing function $\psi_0 : [0, \infty) \to [0, \infty)$ such that

$$\sup \{|\partial f/\partial t(x, t, u)|, |\partial f/\partial u(t, x, u)|\} \leq \psi_0(|x|)(1 + \psi(|u|)|u|)$$

for each $t \in [0, \infty)$, $x, u \in \mathbb{R}^n$.

For the set $\mathcal{M}$ we consider the uniformity which is determined by the the following base

$$E(N, \epsilon, \lambda) = \{(f, g) \in \mathcal{M} \times \mathcal{M} : |f(t, x, u) - g(t, x, u)| \leq \epsilon \}$$

for each $t \in [0, \infty)$, $u \in \mathbb{R}^n$, $x \in K$, $|x|, |u| \leq N$, $\lambda = (N, \epsilon)$.
\[(|f(t, x, u)| + 1)(|g(t, x, u)| + 1)^{-1} \in [\lambda^{-1}, \lambda]\]
\[(t \in [0, \infty), \ u \in \mathbb{R}^n, \ x \in K, \ |x| \leq N)\]

where \(N > 0, \epsilon > 0, \lambda > 1\).

Clearly, the uniform space \(\mathfrak{M}\) is Hausdorff and has a countable base. Therefore \(\mathfrak{M}\) is metrizable. We will show that the uniform space \(\mathfrak{M}\) is complete (see Proposition 2.2).

We consider functionals of the form
\[(1.2) \quad I_f(T_1, T_2, x) = \int_{T_1}^{T_2} f(t, x(t), x'(t)) dt\]
where \(f \in \mathfrak{M}, \ 0 \leq T_1 < T_2 < \infty\) and \(x : [T_1, T_2] \to K\) is an a.c. function.

For \(f \in \mathfrak{M}, \ a, b \in K\) and numbers \(T_1, T_2\) satisfying \(0 \leq T_1 < T_2\) we set
\[(1.3) \quad U_f(T_1, T_2, a, b) = \inf \{I_f(T_1, T_2, x) : x : [T_1, T_2] \to K\}
\text{is an a.c. function satisfying } x(T_1) = a, \ x(T_2) = b\},
\[(1.4) \quad \sigma_f(T_1, T_2, a) = \inf \{U_f(T_1, T_2, a, b) : b \in K\}.
\]
It is easy to see that \(-\infty < U_f(T_1, T_2, a, b) < \infty\) for each \(f \in \mathfrak{M}\), each \(a, b \in K\) and each numbers \(T_1, T_2\) satisfying \(0 \leq T_1 < T_2\).

Here we follow Leizarowitz [10] in defining “good functions” for the variational problem.

Let \(f \in \mathfrak{M}\). An a.c. function \(x : [0, \infty) \to K\) is called an \((f)\)-good function if for any a.c. function \(y : [0, \infty) \to K\) there is a number \(M_y\) such that
\[(1.5) \quad I_f(0, T, y) \geq M_y + I_f(0, T, x) \text{ for each } T \in (0, \infty).\]

In this paper our goal will be to study the set of \((f)\)-good functions. We will establish the following results.

**Theorem 1.1.** For each \(f \in \mathfrak{M}\) and each \(z \in K\) there exists an \((f)\)-good function \(Z^f : [0, \infty) \to K\) satisfying \(Z^f(0) = z\) such that:

1. For each \(f \in \mathfrak{M}, \ eac h \ z \in K\) and each a.c. function \(y : [0, \infty) \to K\) one of the following properties holds:
   \[(i) \quad I_f(0, T, y) - I_f(0, T, Z^f) \to \infty \text{ as } T \to \infty;\]
   \[(ii) \quad \sup\{|I_f(0, T, y) - I_f(0, T, Z^f)| : T \in (0, \infty)\} < \infty,
   \sup\{|y(t)| : t \in [0, \infty)\} < \infty.\]

2. For each \(f \in \mathfrak{M}\) and each number \(M > \inf\{|u| : u \in K\}\) there exist a neighborhood \(U\) of \(f\) in \(\mathfrak{M}\) and a number \(Q > 0\) such that
\[\sup\{|Z^g(t)| : t \in [0, \infty)\} \leq Q\]
for each $g \in U$ and each $z \in K$ satisfying $|z| \leq M$.

3. For each $f \in \mathcal{M}$ and each number $M > \inf\{|u| : u \in K\}$ there exist a
neighborhood $U$ of $f$ in $\mathcal{M}$ and a number $Q > 0$ such that for each $g \in U$,
each $z \in K$ satisfying $|z| \leq M$, each $T_1 \geq 0$, $T_2 > T_1$ and each a.c. function
$y : [T_1, T_2] \to K$ satisfying $|y(T_1)| \leq M$ the following relation holds:

$$I^g(T_1, T_2, Z^g) \leq I^g(T_1, T_2, y) + Q.$$

4. If $K = \mathbb{R}^n$ then for each $f \in \mathcal{M}$ and each $z \in \mathbb{R}^n$ the function
$Z^f : [0, \infty) \to \mathbb{R}^n$ is an $(f)$-minimal solution.

**Corollary 1.1.** Let $f \in \mathcal{M}$, $z \in K$ and let $y : [0, \infty) \to K$ be an a.c.
function. Then $y$ is an $(f)$-good function if and only if condition (ii) of
Assertion 1 holds.

**Theorem 1.2.** For each $f \in \mathcal{M}$ there exists a neighborhood $U$ of $f$ in $\mathcal{M}$
and a number $M > 0$ such that for each $g \in U$ and each $(g)$-good function
$x : [0, \infty) \to K$

$$\limsup_{t \to \infty} |x(t)| < M.$$

In this paper we prove the following result which establishes that for
every bounded set $E \subset K$ the $C([0, T])$ norms of approximate solutions
$x : [0, T] \to K$ for the minimization problem on an interval $[0, T]$ with
$x(0), x(T) \in E$ are bounded by some constant which does not depend on $T$.

**Theorem 1.3.** Let $f \in \mathcal{M}$ and $M_1, M_2, c$ be positive numbers. Then there
exist a neighborhood $U$ of $f$ in $\mathcal{M}$ and a number $S > 0$ such that for each $g \in U$,
each $T_1 \in [0, \infty)$ and each $T_2 \in [T_1 + c, \infty)$ the following properties
hold:

(i) for each $x, y \in K$ satisfying $|x|, |y| \leq M_1$ and each a.c. function
$v : [T_1, T_2] \to K$ satisfying

$$v(T_1) = x, \; v(T_2) = y, \; I^g(T_1, T_2, v) \leq U^g(T_1, T_2, x, y) + M_2$$

the following relation holds:

$$|v(t)| \leq S, \; t \in [T_1, T_2];$$

(ii) for each $x \in K$ satisfying $|x| \leq M_1$ and each a.c. function $v : [T_1, T_2] \to K$ satisfying

$$v(T_1) = x, \; I^g(T_1, T_2, v) \leq \sigma^g(T_1, T_2, x) + M_2$$

relation (1.6) holds.
2. Preliminary results

Proposition 2.1. Let $f \in \mathcal{M}$, $M$ and $\epsilon$ be positive numbers. Then there exist $\Gamma, \delta > 0$ such that

$$|f(t, x_1, u_1) - f(t, x_2, u_2)| \leq \epsilon \inf \{f(t, x_1, u_1), f(t, x_2, u_2)\}$$

for each $t \in [0, \infty)$, each $u_1, u_2 \in \mathbb{R}^n$ and each $x_1, x_2 \in K$ which satisfy

$$|x_i| \leq M, |u_i| \geq \Gamma, i = 1, 2, |u_1 - u_2|, |x_1 - x_2| \leq \delta.$$

Proof. Fix a number

$$\epsilon_0 \in (0, 4^{-1} \inf \{1, \epsilon\}).$$

By Assumption (Aiv) there exist $\Gamma, \delta > 0$ such that

$$|f(t, x_1, u_1) - f(t, x_2, u_2)| \leq \epsilon_0 \sup \{f(t, x_1, u_1), f(t, x_2, u_2)\}$$

for each $t \in [0, \infty)$, each $u_1, u_2 \in \mathbb{R}^n$ and each $x_1, x_2 \in K$ which satisfy (2.1).

Assume that $t \in [0, \infty)$, $u_1, u_2 \in \mathbb{R}^n$ and $x_1, x_2 \in K$ satisfy (2.1). It follows from the definition of $\Gamma, \delta$ and (2.2), (2.3) that

$$\inf \{f(t, x_1, u_1), f(t, x_2, u_2)\} \geq (1 - \epsilon_0) \sup \{f(t, x_1, u_1), f(t, x_2, u_2)\}$$

$$\geq (1 - \epsilon_0) \epsilon_0^{-1} |f(t, x_1, u_1) - f(t, x_2, u_2)| \geq \epsilon^{-1} |f(t, x_1, u_1) - f(t, x_2, u_2)|.$$

The proposition is proved.

Proposition 2.2. The uniform space $\mathcal{M}$ is complete.

Proof. Assume that $\{f_i\}_{i=1}^\infty \subset \mathcal{M}$ is a Cauchy sequence. Clearly, there exists a function $f : [0, \infty) \times K \times \mathbb{R}^n \to \mathbb{R}$ such that for each $(t, x, u) \in [0, \infty) \times K \times \mathbb{R}^n$

$$f(t, x, u) = \lim_{i \to \infty} f_i(t, x, u).$$

To prove the proposition it is sufficient to show that $f$ satisfies Assumption (Aiv).

Let $M, \epsilon$ be positive numbers. Fix a number $\lambda > 1$ such that

$$\lambda^2 - 1 < 8^{-1} \epsilon.$$

Clearly there exists an integer $j \geq 1$ such that

$$\{f_i, f_j\} \in E(M, \epsilon, \lambda) \text{ for any integer } i \geq j.$$
By (2.5) and the properties of $\psi$ there exists a number $\Gamma_0$ such that

$$ (2.7) \quad \Gamma_0 > 1, \quad \psi(\Gamma_0) \geq 2a, \quad \lambda^2(1 + 2\psi(\Gamma_0)^{-1})^2 - 1 < 8^{-1}\epsilon. $$

Fix a positive number $\epsilon_1$ which satisfies

$$ (2.8) \quad 8\epsilon_1|\lambda(1 + 2\psi(\Gamma_0)^{-1})|^2 < \epsilon. $$

By Proposition 2.1 there exist numbers $\Gamma, \delta > 0$ such that

$$ (2.9) \quad \Gamma > \Gamma_0, \quad |f_j(t, x_1, u_1) - f_j(t, x_2, u_2)| \leq \epsilon_1 \inf \{f_j(t, x_1, u_1), f_j(t, x_2, u_2)\} $$

for each $t \in [0, \infty)$, each $u_1, u_2 \in \mathbb{R}^n$ and each $x_1, x_2 \in K$ which satisfy (2.1).

Assume that $t \in [0, \infty), \; u_1, u_2 \in \mathbb{R}^n, \; x_1, x_2 \in K$ satisfy (2.1). It follows from the definition of $\Gamma, \delta$ that (2.9) holds. By (1.1), (2.4), (2.6) and (2.1)

$$ (2.10) \quad (|f(t, x_i, u_i)| + 1)(|f_j(t, x_i, u_i)| + 1)^{-1} \in [\lambda^{-1}, \lambda], \quad i = 1, 2. $$

Assumption (Aiii), (2.1), (2.7) and (2.9) imply that

$$ (2.11) \quad \inf \{f(t, x_i, u_i), f_j(t, x_i, u_i)\} \geq 2^{-1}\psi(\Gamma_0), \; i = 1, 2. $$

Together with (2.10) this implies that

$$ (2.12) \quad f(t, x_i, u_i)f_j(t, x_i, u_i)^{-1} \in [(\lambda(1 + 2\psi(\Gamma_0)^{-1}))^{-1}, \lambda(1 + 2\psi(\Gamma_0)^{-1})], \; i = 1, 2. $$

We may assume without loss of generality that

$$ (2.13) \quad f(t, x_1, u_1) \geq f(t, x_2, u_2). $$

It follows from (2.12), (2.9), (2.8) and (2.7) that

$$ f(t, x_1, u_1) - f(t, x_2, u_2) \leq \lambda(1 + 2\psi(\Gamma_0)^{-1})f_j(t, x_1, u_1) $$

$$ -\lambda(1 + 2\psi(\Gamma_0)^{-1})^{-1}f_j(t, x_2, u_2) = \lambda(1 + 2\psi(\Gamma_0)^{-1})[f_j(t, x_1, u_1) - $$

$$ f_j(t, x_2, u_2)] + f_j(t, x_2, u_2)[\lambda(1 + 2\psi(\Gamma_0)^{-1}) - (\lambda(1 + 2\psi(\Gamma_0)^{-1}))^{-1}] $$

$$ \leq \lambda(1 + 2\psi(\Gamma_0)^{-1})\epsilon_1f_j(t, x_2, u_2) + f_j(t, x_2, u_2)[\lambda(1 + 2\psi(\Gamma_0)^{-1}) - $$

$$ (\lambda(1 + 2\psi(\Gamma_0)^{-1}))^{-1}] \leq \epsilon_1[\lambda(1 + 2\psi(\Gamma_0)^{-1})]^2f(t, x_2, u_2) + $$

$$ f(t, x_2, u_2)[\lambda^2(1 + 2\psi(\Gamma_0)^{-1})^2 - 1] \leq \epsilon f(t, x_2, u_2). $$

Therefore the function $f$ satisfies Assumption (Aiv). This completes the proof of the proposition. $\blacksquare$
Proposition 2.3. Let $M_1 > 0$, $0 < \tau_0 < \tau_1$. Then there exists a number $M_2 > 0$ such that for each $f \in \mathcal{M}$, each pair of numbers $T_1, T_2$ satisfying
\begin{equation}
0 \leq T_1 < T_2, \quad T_2 - T_1 \in [\tau_0, \tau_1]
\end{equation}
and each a.c. function $x : [T_1, T_2] \rightarrow K$ which satisfies
\begin{equation}
I^f(T_1, T_2, x) \leq M_1
\end{equation}
the following relation holds:
\begin{equation}
|x(t)| \leq M_2, \quad t \in [T_1, T_2].
\end{equation}

Proof. By Assumption (Aiii) and the properties of the function $\psi$ there exists a number $c_0 > 0$ such that
\begin{equation}
f(t, x, u) \geq |u|
\end{equation}
for each $f \in \mathcal{M}$ and each $(t, x, u) \in [0, \infty) \times K \times \mathbb{R}^n$ satisfying $|u| \geq c_0$, and
\begin{equation}
f(t, x, u) \geq 2M_1 (\inf\{1, \tau_0\})^{-1}
\end{equation}
for each $f \in \mathcal{M}$ and each $(t, x, u) \in [0, \infty) \times K \times \mathbb{R}^n$ satisfying $|x| \geq c_0$. Fix a number
\begin{equation}
M_2 > 1 + M_1 + a\tau_1 + c_0(1 + \tau_1)
\end{equation}
(recall $a$ in Assumption (Aiii)).

Let $f \in \mathcal{M}$, $T_1, T_2$ be numbers satisfying (2.14) and let $x : [T_1, T_2] \rightarrow K$ be an a.c. function satisfying (2.15). We will show that (2.16) holds.

Assume the contrary. Then there exists $t_0 \in [T_1, T_2]$ such that
\begin{equation}
|x(t_0)| > M_2.
\end{equation}

By the definition of $c_0$, (2.18), (2.14) and (2.15) there exists $t_1 \in [T_1, T_2]$ satisfying
\begin{equation}
|x(t_1)| \leq c_0.
\end{equation}

Set
\begin{equation}
E = \{t_0, t_1\}, \quad E_1 = \{t \in E : |x'(t)| \geq c_0\}, \quad E_2 = E \setminus E_1.
\end{equation}

It follows from (2.22), (2.14), the definition of $c_0$, (2.17), Assumption (Aiii) and (2.15) that
\begin{align*}
|x(t_1) - x(t_0)| &\leq \int_{E_1} |x'(t)|dt + \int_{E_2} |x'(t)|dt \\
&\leq \tau_1 c_0 + \int_{E_1} |x'(t)|dt \\
&\leq \tau_1 c_0 + \int_{E_1} f(t, x(t), x'(t))dt \\
&\leq \tau_1 c_0 + I^f(T_1, T_2, x) + a\tau_1 \leq \tau_1 (c_0 + a) + M_1.
\end{align*}

By this relation and (2.20), (2.21) $M_2 - c_0 \leq \tau_1 (c_0 + a) + M_1$. This is contradictory to (2.19). The obtained contradiction proves the proposition. \( \blacksquare \)
Proposition 2.4. Let $M_1, \epsilon > 0$, $0 < \tau_0 < \tau_1$. Then there exists a number $\delta > 0$ such that for each $f \in \mathcal{M}$, each numbers $T_1, T_2$ satisfying (2.14), each a.c. function $x : [T_1, T_2] \to K$ satisfying (2.15) and each $t_1, t_2 \in [T_1, T_2]$ which satisfy $|t_1 - t_2| \leq \delta$ the relation $|x(t_1) - x(t_2)| \leq \epsilon$ holds.

Proof. By Assumption (Aiii) and the properties of the function $\psi$ there exists a number $c_0 > 0$ such that

(2.23) \[ f(t, x, u) \geq 4\epsilon^{-1}(M_1 + 2 + a\tau_1)|u| \]

for each $f \in \mathcal{M}$ and each $(t, x, u) \in [0, \infty) \times K \times \mathbb{R}^n$ satisfying $|u| \geq c_0$. Fix a number

(2.24) \[ \delta \in (0, 8^{-1}(c_0 + 1)^{-1}\epsilon). \]

Assume that $f \in \mathcal{M}$, numbers $T_1, T_2$ satisfy (2.14), an a.c. function $x : [T_1, T_2] \to K$ satisfies (2.15) and

(2.25) \[ t_1, t_2 \in [T_1, T_2], \ 0 < |t_1 - t_2| \leq \delta. \]

Set

\[ E = [\inf\{t_1, t_2\}, \sup\{t_1, t_2\}], \ E_1 = \{t \in E : |x'(t)| \geq c_0\}, \ E_2 = E \setminus E_1. \]

It follows from (2.25), the definition of $c_0$, (2.23), (2.14) and Assumption (Aiii) that

\[
|x(t_2) - x(t_1)| \leq \int_{E_1} |x'(t)|dt + \int_{E_2} |x'(t)|dt \leq \delta c_0 + \int_{E_1} |x'(t)|dt
\]

\[
\leq \delta c_0 + [4(M_1 + 2 + a\tau_1)]^{-1} \epsilon \int_{E_1} f(t, x(t), x'(t))dt
\]

\[
\leq \delta c_0 + [4(M_1 + 2 + a\tau_1)]^{-1} \epsilon (I^f(T_1, T_2, x) + a\tau_1).
\]

Together with (2.15), (2.14) and (2.24) this relation implies that

\[
|x(t_2) - x(t_1)| \leq \delta c_0 + 4^{-1}\epsilon \leq \epsilon.
\]

This completes the proof of the proposition. ■

We have the following result (see Berkovitz [4]).

Proposition 2.5. Assume that $f \in \mathcal{M}$, $M_1 > 0$, $0 \leq T_1 < T_2$, $x_i : [T_1, T_2] \to K$, $i = 1, 2, \ldots$ is a sequence of a.c. functions such that

\[ I^f(T_1, T_2, x_i) \leq M_1, \ i = 1, 2, \ldots \]

Then there exists a subsequence $\{x_{i_k}\}_{k=1}^\infty$ and an a.c. function $x : [T_1, T_2] \to K$ such that

\[ I^f(T_1, T_2, x) \leq M_1, \ x_{i_k} \to x(t) \text{ as } k \to \infty \text{ uniformly in } [T_1, T_2] \text{ and} \]

\[ x'_{i_k} \to x' \text{ as } k \to \infty \text{ weakly in } L^1(R^n; (T_1, T_2)). \]
Corollary 2.1. For each \( f \in M \), each pair of numbers \( T_1, T_2 \) satisfying \( 0 \leq T_1 < T_2 \) and each \( z_1, z_2 \in K \) there exists an a.c. function \( x : [T_1, T_2] \to K \) such that \( x(T_i) = z_i, \ i = 1, 2 \).

Corollary 2.2. For each \( f \in M \), each \( T_1, T_2 \) satisfying \( 0 \leq T_1 < T_2 \) and each \( z \in K \) there exists an a.c. function \( x : [T_1, T_2] \to K \) such that \( x(T_1) = z, I^f(T_1, T_2, x) = \sigma^f(T_1, T_2, z) \).

It is an elementary exercise to prove the following result.

Proposition 2.6. Let \( f \in M \), \( 0 < c_1 < c_2 < \infty \) and let \( c_3 > 0 \). Then there exists a neighborhood \( U \) of \( f \) in \( M \) such that the set

\[
\{ U^g(T_1, T_2, z_1, z_2) : g \in U, T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], \]
\[
z_1, z_2 \in K, |z_i| \leq c_3, i = 1, 2 \}
\]

is bounded.

Proposition 2.7. Assume that \( K = \mathbb{R}^n \), \( f \in M \), \( 0 < c_1 < c_2 < \infty \) and \( M, \epsilon > 0 \). Then there exists \( \delta > 0 \) such that for each \( T_1, T_2 \geq 0 \) satisfying

\[
T_2 - T_1 \in [c_1, c_2]
\]

and each \( y_1, y_2, z_1, z_2 \in \mathbb{R}^n \) satisfying

\[
|y_i|, |z_i| \leq M, i = 1, 2, \ \sup\{|y_1 - y_2|, |z_1 - z_2|\} \leq \delta
\]

the following relation holds:

\[
|U^f(T_1, T_2, y_1, z_1) - U^f(T_1, T_2, y_2, z_2)| \leq \epsilon.
\]

Proof. By Proposition 2.6 there exists a number

\[
(2.29) \quad M_0 > \sup\{|U^f(T_1, T_2, y, z)| : T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], \}
\]
\[
y, z \in \mathbb{R}^n, |y|, |z| \leq M \}.
\]

By Proposition 2.3 there exists a number \( M_1 > 0 \) such that for each pair of numbers \( T_1, T_2 \geq 0 \) satisfying (2.26) and each a.c. function \( x : [T_1, T_2] \to \mathbb{R}^n \) which satisfies \( I^f(T_1, T_2, x) \leq 4M_0 + 1 \) the following relation holds:

\[
(2.30) \quad |x(t)| \leq M_1, t \in [T_1, T_2].
\]

Choose a number \( \delta_1 > 0 \) such that

\[
(2.31) \quad 4\delta_1(2c_2 + 2a + 4ac_2 + 1 + M_0) < \epsilon
\]
(see Assumption (Aiii)). By Proposition 2.1 there exist
\begin{equation}
\Gamma_0 > 2 \text{ and } \delta_2 \in (0, 8^{-1})
\end{equation}
such that
\begin{equation}
|f(t, x_1, u_1) - f(t, x_2, u_2)| \leq \delta_1 \inf \{f(t, x_1, u_1), f(t, x_2, u_2)\}
\end{equation}
for each $t \in [0, \infty)$ and each $u_1, u_2, x_1, x_2 \in \mathbb{R}^n$ which satisfy
\begin{equation}
|x_i| \leq M_1 + 1, \ |u_i| \geq \Gamma_0 - 1, \ i = 1, 2, \ |u_1 - u_2|, |x_1 - x_2| \leq \delta_2.
\end{equation}
By Assumption (Aiv) there is a number
\begin{equation}
\delta_3 \in (0, 4^{-1} \inf \{\delta_1, \delta_2\})
\end{equation}
such that
\begin{equation}
|f(t, x_1, u_1) - f(t, x_2, u_2)| \leq \delta_1
\end{equation}
for each $t \in [0, \infty)$, each $u_1, u_2, x_1, x_2 \in \mathbb{R}^n$ which satisfy
\begin{equation}
|x_i|, |u_i| \leq \Gamma_0 + M_1 + 4, \ |u_1 - u_2|, |x_1 - x_2| \leq \delta_3.
\end{equation}
There exists a positive number $\delta$ such that
\begin{equation}
8(c_1^{-1} + 1)\delta < \delta_3.
\end{equation}

Assume that numbers $T_1, T_2 \geq 0$ satisfy (2.26) and $y_1, y_2, z_1, z_2 \in \mathbb{R}^n$ satisfy (2.27). By Corollary 2.1 there exists an a.c. function $x_1 : [T_1, T_2] \to \mathbb{R}^n$ such that
\begin{equation}
x_1(T_1) = y_1, \ x_1(T_2) = z_1, \ I^f(T_1, T_2, x_1) = U^f(T_1, T_2, y_1, z_1).
\end{equation}
Set
\begin{equation}
x_2(t) = x_1(t) + y_2 - y_1 + (t - T_1)(T_2 - T_1)^{-1}(z_2 - z_1 - y_2 + y_1), \ t \in [T_1, T_2].
\end{equation}
Clearly
\begin{equation}
x_2(T_1) = y_2, \ x_2(T_2) = z_2.
\end{equation}
It follows from (2.26), (2.27), (2.39), (2.29) and the definition of $M_1$ that
\begin{equation}
|x_1(t)| \leq M_1, \ t \in [T_1, T_2].
\end{equation}
(2.40), (2.27) and (2.26) imply that

\[(2.43) \quad |x_1(t) - x_2(t)| \leq 3\delta, \quad |x'_1(t) - x'_2(t)| \leq 2c_1^{-1}\delta, \quad t \in [T_1, T_2].\]

Set

\[(2.44) \quad E_1 = \{t \in [T_1, T_2] : |x'_1(t)| \geq \Gamma_0\}, \quad E_2 = [T_1, T_2] \setminus E_1.\]

We have

\[(2.45) \quad |I^f(T_1, T_2, x_2) - I^f(T_1, T_2, x_1)| \leq \sigma_1 + \sigma_2\]

where

\[(2.46) \quad \sigma_j = \int_{E_j} |f(t, x_1(t), x'_1(t)) - f(t, x_2(t), x'_2(t))| dt, \quad j = 1, 2.\]

We will estimate \(\sigma_1, \sigma_2\) separately. Let \(t \in E_1\). It follows from (2.42), (2.43), (2.44), (2.38), (2.35), (2.32) and the definition of \(\delta_2\) that

\[|f(t, x_1(t), x'_1(t)) - f(t, x_2(t), x'_2(t))| \leq \delta_1 f(t, x_1(t), x'_1(t)).\]

Therefore \(\sigma \leq \delta_1 \int_{E_1} f(t, x_1(t), x'_1(t)) dt\). This relation, Assumption (Aiii), (2.39), (2.27), (2.29) and (2.26) imply that

\[(2.47) \quad \sigma_1 \leq \delta_1 (I^f(T_1, T_2, x_1) + a(T_2 - T_1)) \leq \delta_1 (M_0 + ac_2).\]

Let \(t \in E_2\). It follows from (2.42), (2.43), (2.38), (2.44) and the definition of \(\delta_3\) that

\[|f(t, x_1(t), x'_1(t)) - f(t, x_2(t), x'_2(t))| \leq \delta_1.\]

Therefore

\[(2.48) \quad \sigma_2 \leq \delta_1 c_2.\]

Combining (2.45), (2.47), (2.48) and (2.31) we obtain that

\[|I^f(T_1, T_2, x_2) - I^f(T_1, T_2, x_1)| \leq \delta_1 (M_0 + ac_2 + c_2) \leq \epsilon.\]

Together with (2.39) and (2.41) this implies that

\[U^f(T_1, T_2, y_2, z_2) \leq U^f(T_1, T_2, y_1, z_1) + \epsilon.\]

This completes the proof of the proposition.
Proposition 2.8. Let \( f \in \mathcal{M} \), \( 0 < c_1 < c_2 < \infty \), \( D, \epsilon > 0 \). Then there exists a neighborhood \( V \) of \( f \) in \( \mathcal{M} \) such that for each \( g \in V \), each pair of numbers \( T_1, T_2 \geq 0 \) satisfying \( T_2 - T_1 \in [c_1, c_2] \) and each a. c. function \( x : [T_1, T_2] \to K \) satisfying

\[
(2.49) \quad \inf \{I^f(T_1, T_2, x), I^g(T_1, T_2, x)\} \leq D
\]

the relation \(|I^f(T_1, T_2, x) - I^g(T_1, T_2, x)| \leq \epsilon\) holds.

Proof. By Proposition 2.3 there exists a number \( S > 0 \) such that for each \( g \in \mathcal{M} \), each \( T_1, T_2 \geq 0 \) satisfying \( T_2 - T_1 \in [c_1, c_2] \) and each a.c. function \( x : [T_1, T_2] \to K \) which satisfies \( I^g(T_1, T_2, x) \leq D + 1 \) the following relation holds:

\[
(2.50) \quad |x(t)| \leq S, \ t \in [T_1, T_2].
\]

There exist \( \delta \in (0, 1), N > S \) and \( \Gamma > 1 \) such that

\[
(2.51) \quad \delta(c_2 + 1) \leq 4^{-1}\epsilon, \psi(N)N > 4a, (\Gamma - 1)(c_2 + D + ac_2 + 1) \leq 4^{-1}\epsilon.
\]

Set \( V = \{g \in \mathcal{M} : (f, g) \in E(N, \delta, \Gamma)\} \) (see (1.1)). Assume that \( g \in V \),

\[
(2.52) \quad T_1, T_2 \geq 0, \ T_2 - T_1 \in [c_1, c_2]
\]

and \( x : [T_1, T_2] \to K \) is an a.c. function satisfying (2.49). It follows from the definition of \( S \) that (2.50) holds. Set

\[
E_1 = \{t \in [T_1, T_2] : |x'(t)| \leq N\}, \ E_2 = [T_1, T_2] \setminus E_1.
\]

It follows from (2.50) and the definition of \( V \) and \( N \) that

\[
(2.53) \quad |f(t, x(t), x'(t)) - g(t, x(t), x'(t))| \leq \delta, \ t \in E_1.
\]

Define

\[
(2.54) \quad h(t) = \inf \{f(t, x(t), x'(t)), \ g(t, x(t), x'(t))\}, \ t \in [T_1, T_2].
\]

It follows from (2.50), (2.51), Assumption (Aiii) and the definition of \( V, N \) that for \( t \in E_2 \)

\[
(2.55) \quad (f(t, x(t), x'(t)) + 1)(g(t, x(t), x'(t)) + 1)^{-1} \in [\Gamma^{-1}, \Gamma],
\]

\[
|f(t, x(t), x'(t)) - g(t, x(t), x'(t))| \leq (\Gamma - 1)(h(t) + 1).
\]

By (2.53), (2.52), (2.55), (2.49), (2.54), Assumption (Aiii) and (2.51)

\[
|I^f(T_1, T_2, x) - I^g(T_1, T_2, x)| \leq \int_{E_1} |f(t, x(t), x'(t)) - g(t, x(t), x'(t))|dt + \int_{E_2} |f(t, x(t), x'(t)) - g(t, x(t), x'(t))|dt \leq \delta c_2 + (\Gamma - 1) \int_{E_2} (h(t) + 1)dt
\]

\[
\leq \delta c_2 + (\Gamma - 1)c_2 + (\Gamma - 1)(D + ac_2) \leq \epsilon.
\]

The proposition is proved. \( \blacksquare \)
Proposition 2.9. Let $f \in \mathcal{M}$, $0 < c_1 < c_2 < \infty$, $c_3, \epsilon > 0$. Then there exists a neighborhood $V \subset \mathcal{M}$ such that for each $g \in V$, each $T_1, T_2 \geq 0$ satisfying $T_2 - T_1 \in [c_1, c_2]$ and each $y, z \in K$ satisfying $|y|, |z| \leq c_3$ the relation

$$|U^f(T_1, T_2, y, z) - U^g(T_1, T_2, y, z)| \leq \epsilon$$

holds.

Proof. By Proposition 2.6 there exist a neighborhood $V_1$ of $f$ in $\mathcal{M}$ and a number

$$D_0 = \sup\{|U^g(T_1, T_2, z_1, z_2)| : g \in V_1, T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], z_1, z_2 \in K, |z_i| \leq c_3, i = 1, 2\}.$$

By Proposition 2.8 there exists a neighborhood $V$ of $f$ in $\mathcal{M}$ such that $V \subset V_1$ and for each $g \in V$, each $T_1, T_2 \geq 0$ satisfying $T_2 - T_1 \in [c_1, c_2]$ and each a.c. function $x : [T_1, T_2] \to K$ satisfying

$$\inf\{|I^f(T_1, T_2, x), I^g(T_1, T_2, x)| \leq D_0 + 2$$

the relation $|I^f(T_1, T_2, x) - I^g(T_1, T_2, x)| \leq \inf\{1, \epsilon\}$ holds.

To complete the proof it remains now to note that for $g \in V$, $T_1 \geq 0$, $T_2 \in [T_1 + c_1, T_1 + c_2]$ and $y, z \in K$ satisfying $|y|, |z| \leq c_3$ the following relation holds:

$$U^g(T_1, T_2, y, z) = \inf\{I^g(T_1, T_2, x) : x : [T_1, T_2] \to K \text{ is an a.c. function satisfying } x(T_1) = y, x(T_2) = z, I^g(T_1, T_2, x) \leq D_0 + 1\}.$$

3. Discrete-time control systems

Let $f \in \mathcal{M}$, $\bar{z} \in K$ and let $0 < c_1 < c_2 < \infty$. By Proposition 2.6 there exists a neighborhood $U_0$ of $f$ in $\mathcal{M}$ and a number

$$M_0 = \sup\{|U^g(T_1, T_2, y, z)| : g \in U_0, T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], y, z \in K, |y|, |z| \leq 2|\bar{z}| + 1\}.$$

By Proposition 2.3 there exists a positive number $M_1$ such that

$$\inf\{U^g(T_1, T_2, y, z) : g \in \mathcal{M}, T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], y, z \in K, |y| + |z| \geq M_1\} > 2M_0 + 1.$$
Proposition 3.1. Assume that a positive number $M_1$ satisfies (3.2) and $M_2 > 0$. Then there exists a neighborhood $U$ of $f$ in $\mathfrak{M}$ and an integer $N > 2$ such that:
1. For each $g \in U$, each $\Delta \in [0, \infty)$, each $T \in [c_1, c_2]$, each pair of integers $q_1, q_2$ satisfying $0 \leq q_1 < q_2$, $q_2 - q_1 \geq N$ and each sequence $\{z_i\}_{i=q_1}^{q_2} \subset K$ satisfying
   \[ \{i \in \{q_1, \ldots, q_2\} : |z_i| \leq M_1\} = \{q_1, q_2\} \]
the following relation holds:
\begin{equation}
q_2^{-1} \sum_{i=q_1}^{q_2-1} [U^g(\Delta+iT, \Delta+(i+1)T, z_i, z_{i+1}) - U^g(\Delta+iT, \Delta+(i+1)T, y_i, y_{i+1})] \geq M_2
\end{equation}
where $y_i = z_i, i = q_1, q_2, y_1 = \bar{z}, i = q_1 + 1, \ldots, q_2 - 1$;
2. For each $g \in U$, each $\Delta \in [0, \infty)$, each $T \in [c_1, c_2]$, each pair of integers $q_1, q_2$ satisfying $0 \leq q_1 < q_2$, $q_2 - q_1 \geq N$ and each sequence $\{z_i\}_{i=q_1}^{q_2} \subset K$ satisfying
   \[ \{i \in \{q_1, \ldots, q_2\} : |z_i| \leq M_1\} = \{q_1\} \]
relation (3.3) holds with $y_{q_1} = z_{q_1}, y_i = \bar{z}, i = q_1 + 1, \ldots, q_2$.

Proof. By Proposition 2.6 there exists a neighborhood $U$ of $f$ in $\mathfrak{M}$ and a number $M_3 > 0$ such that
\[ U \subset U_0, \quad M_3 \geq \sup\{|U^g(T_1, T_2, y, z)| : g \in U, T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], y, z \in K, |y|, |z| \leq 2|\bar{z}| + 1 + 2M_1\} \]
Fix an integer $N \geq M_2 + 4M_3 + 4$. The validity of the proposition now follows from the definition of $U$, $M_3$, $N$ and (3.1), (3.2). $\blacksquare$

Proposition 3.2. Assume that a positive number $M_1$ satisfies (3.2) and $M_3 > 0$. Then there exists a neighborhood $V$ of $f$ in $\mathfrak{M}$ and a number $M_4 > M_1$ such that:
1. For each $g \in V$, each $\Delta \in [0, \infty)$, each $T \in [c_1, c_2]$, each pair of integers $q_1, q_2$ satisfying $0 \leq q_1 < q_2$ and each sequence $\{z_i\}_{i=q_1}^{q_2} \subset K$ satisfying
   \begin{equation}
   \sup\{|z_{q_1}, |z_{q_2}|\} \leq M_1, \quad \sup\{|z_i| : i = q_1, \ldots, q_2\} > M_4
   \end{equation}
there is a sequence $\{y_i\}_{i=q_1}^{q_2} \subset K$ which satisfies $y_{q_1} = z_{q_1}, j = 1, 2$,
\begin{equation}
q_2^{-1} \sum_{i=q_1}^{q_2-1} [U^g(\Delta+iT, \Delta+(i+1)T, z_i, z_{i+1}) - U^g(\Delta+iT, \Delta+(i+1)T, y_i, y_{i+1})] \geq M_3
\end{equation}
2. For each $g \in V$, each $\Delta \in [0, \infty)$, each $T \in [c_1, c_2]$, each pair of integers $q_1, q_2$ satisfying $0 \leq q_1 < q_2$ and each sequence $\{z_i\}_{i=q_1}^{q_2} \subset K$ satisfying
   \begin{equation}
   |z_{q_1}| \leq M_1, \quad \sup\{|z_i| : i = q_1, \ldots, q_2\} > M_4
   \end{equation}
there is a sequence \( \{y_i\}_{i=q_1}^{q_2} \subset K \) which satisfies \( y_{q_1} = z_{q_1} \) and (3.5).

**Proof.** There exist a neighborhood \( U \) of \( f \) in \( \mathfrak{M} \) and an integer \( N > 2 \) such that Proposition 3.1 holds with \( M_2 = 4(M_3 + 1) \) and \( U \subset U_0 \). By Proposition 2.6 there exist a neighborhood \( V \) of \( f \) in \( \mathfrak{M} \) and a number \( r_1 \) such that

\[
V \subset U, \quad r_1 > \sup\{|U^g(T_1, T_2, y, z)| : g \in V, \ T_1 \in [0, \infty), \ T_2 \in [T_1 + c_1, T_1 + c_2], \ y, z \in K, \ |y|, |z| \leq |\bar{z}| + 1 + M_1\}.
\]

By Proposition 2.3 there exists a positive number \( M_4 > M_1 \) such that

\[
\inf\{U^g(T_1, T_2, y, z) : g \in \mathfrak{M}, \ T_1 \in [0, \infty), \ T_2 \in [T_1 + c_1, T_1 + c_2], \ y, z \in K, |y| + |z| \geq M_4\} > 3r_1N + 4 + 4M_3 + 3ac_2N
\]

(recall \( a \) in Assumption (Aiii)).

We will prove Assertion 1. Let \( g \in V, \Delta \in [0, \infty), \ T \in [c_1, c_2], \ 0 \leq q_1 < q_2, \ \{z_i\}_{i=q_1}^{q_2} \subset K \). Assume that (3.4) holds. Then there is \( j \in \{q_1, \ldots, q_2\} \) such that \( |z_j| > M_4 \). Set

\[
i_1 = \sup\{i \in \{q_1, \ldots, j\} : |z_i| \leq M_1\}, \quad i_2 = \inf\{i \in \{j, \ldots, q_2\} : |z_i| \leq M_1\}.
\]

If \( i_2 - i_1 \geq N \) then by the definition of \( V, U, N \) and Proposition 3.1 there exists a sequence \( \{y_i\}_{i=q_1}^{q_2} \subset K \) which satisfies (3.5) and \( y_{q_1} = z_{q_1}, \ i = 1, 2 \). Assume that \( i_2 - i_1 < N \) and define a sequence \( \{y_i\}_{i=q_1}^{q_2} \subset K \) by

\[
y_i = z_i, \ i \in \{q_1, \ldots, i_1\} \cup \{i_2, \ldots, q_2\}, \ y_i = \bar{z}, \ i = i_1 + 1 \ldots i_2 - 1.
\]

It follows from (3.9), (3.7), Assumption (Aiii) and the definition of \( i_1, i_2, j \) that

\[
\sum_{i=q_1}^{q_2-1} [U^g(\Delta + iT, \Delta + (i + 1)T, z_i, z_{i+1}) - U^g(\Delta + iT, \Delta + (i + 1)T, y_i, y_{i+1})]
\]

\[
= \sum_{i=i_1}^{i_2-1} [U^g(\Delta + iT, \Delta + (i + 1)T, z_i, z_{i+1}) - U^g(\Delta + iT, \Delta + (i + 1)T, y_i, y_{i+1})]
\]

\[
\geq U^g(\Delta + (j - 1)T, \Delta + jT, z_{j-1}, z_j) - a(i_2 - i_1 - 1)c_2 - (i_2 - i_1)r_1.
\]

By this relation and the definition of \( j, M_4 \) (see (3.8))

\[
\sum_{i=q_1}^{q_2-1} [U^g(\Delta + iT, \Delta + (i + 1)T, z_i, z_{i+1}) -
\]
\[ U^g(\Delta + iT, \Delta + (i+1)T, y_i, y_{i+1}) \geq 4M_3 + 4. \]

This completes the proof of Assertion 1.

We will prove Assertion 2. Let \( g \in V, \Delta \in [0, \infty), T \in [c_1, c_2], 0 \leq q_1 < q_2, \{ z_i \}_{i=q_1}^{q_2} \subset K. \) Assume that (3.6) holds. Then there is \( j \in \{ q_1, \ldots, q_2 \} \) such that \( |z_j| > M_4. \) Set \( i_1 = \sup \{ i \in \{ q_1, \ldots, j \} : |z_i| \leq M_1 \}. \)

There are two cases: 1) \( |z_i| > M_1, \ i = j, \ldots, q_2; \) 2) \( \inf \{ |z_i| : \ i = j, \ldots, q_2 \} \leq M_1. \) Consider the first case. We set \( y_i = z_i, \ i = q_1, \ldots, i_1, \ y_i = \bar{z}, \ i = i_1 + 1, \ldots q_2. \)

If \( q_2 - i_1 \geq N \) then (3.5) follows from the definition of \( V, U, N \) and Proposition 3.1. If \( q_2 - i_1 < N \) then (3.5) follows from the definition of \( \{ y_i \}_{i=q_1}^{q_2}, i_1, j, M_4, (3.7) \) (see (3.10), (3.11) with \( i_2 = q_2 \)).

Consider the second case. Set \( i_2 = \inf \{ i \in \{ j, \ldots, q_2 \} : |z_i| \leq M_1 \}. \) If \( i_2 - i_1 \geq N \) then by the definition of \( V, U, N \) and Proposition 3.1 there exists a sequence \( \{ y_i \}_{i=q_1}^{q_2} \subset K \) which satisfies (3.5) and \( y_q = z_q, \ i = 1, 2. \) If \( i_2 - i_1 < N \) we define a sequence \( \{ y_i \}_{i=q_1}^{q_2} \subset K \) by (3.9). Then (3.10) and (3.11) follows from (3.9), the definition of \( i_1, i_2, j, M_4, (3.7). \) Assertion 2 is proved. This completes the proof of the proposition.

4. Proof of Theorems 1.1-1.3

Construction of a neighborhood \( U. \) Let \( f \in \mathfrak{M}, \bar{z} \in K, M > 2|\bar{z}|. \) By Proposition 2.6 there exist a neighborhood \( U_0 \) of \( f \) in \( \mathfrak{M} \) and a number

\[
(4.1) \quad M_0 \geq \sup \{ |U^g(T_1, T_2, y, z)| : g \in U_0, \ T_1 \in [0, \infty), \]

\[ T_2 \in [T_1 + 4^{-1}, T_1 + 4], \ y, z \in K, |y|, |z| \leq 2|\bar{z}| + 1 \}.
\]

By Proposition 2.3 there exists a number \( M_1 > M \) such that

\[
(4.2) \quad \inf \{ U^g(T_1, T_2, y, z) : g \in \mathfrak{M}, \ T_1 \in [0, \infty), \ T_2 \in [T_1 + 4^{-1}, T_1 + 4], \]

\[ y, z \in K, |y| + |z| \geq M_1 \} > 2M_0 + 1. \]

By (4.1), (4.2) there exists a neighborhood \( U_1 \) of \( f \) in \( \mathfrak{M} \) and a number \( M_2 \) such that

\[
(4.3) \quad U_1 \subset U_0, \ M_2 > M_1 \text{ and Proposition 3.2 holds with } M_3 = 1, \]

\[ c_1 = 4^{-1}, \ c_2 = 4, \ V = U_1, \ M_4 = M_2. \]

By Proposition 2.6 there exist a neighborhood \( U_2 \) of \( f \) in \( \mathfrak{M} \) and a number \( Q_0 > 0 \) such that

\[
(4.4) \quad U_2 \subset U_1, \ Q_0 > \sup \{ |U^g(T_1, T_2, y, z)| : g \in U_2, \ T_1 \in [0, \infty), \]

There exists a subsequence
\[ Q \]
\[ Z \]
x
\[ (4.7) \]
\[ U \]
\[ g \]
(4.12)
By Proposition 2.3 there exists a number
\begin{equation}
Q_1 > Q_0 + M_2 + 1
\end{equation}
such that
\begin{equation}
|x(t)| \leq Q_1, \ t \in [T_1, T_2]
\end{equation}
for each \( g \in \mathcal{M} \), each \( T_1, T_2 \) satisfying
\[ 0 \leq T_1 < T_2, \ T_2 - T_1 \in [4^{-1}, 4] \]
and each a.c. function \( x : [T_1, T_2] \to K \) which satisfies \( I^g(T_1, T_2, x) \leq 2Q_0 + 2 \).

By Proposition 2.6 there exist a neighborhood \( U \) of \( f \) in \( \mathcal{M} \) and a number \( Q_2 > 0 \) such that
\begin{equation}
U \subset U_2, \ Q_2 > Q_1, \ Q_2 > \sup\{|U^g(T_1, T_2, y, z)| : g \in U, T_1 \in [0, \infty), \ T_2 \in [T_1 + 4^{-1}, T_1 + 4], \ y, z \in K, |y|, |z| \leq 2Q_1 + 4\}
\end{equation}
We may assume without loss of generality that there exists a number
\begin{equation}
Q_3 > \sup\{|g(t, y, u)| : g \in U, t \in [0, \infty), y \in K, u \in \mathbb{R}^n, |y|, |u| \leq 2M_2 + 2\}.
\end{equation}

\textit{Construction of a function} \( Z^g : [0, \infty) \to K \). Let \( g \in U, z \in K, |z| \leq M \).

By Corollary 2.2 for any integer \( q \geq 1 \) there exists an a.c. function \( Z_q^g : [0, q] \to K \) such that
\begin{equation}
Z_q^g(0) = z, \ I^g(0, q, Z_q^g) = \sigma^g(0, q, z).
\end{equation}
It follows from Proposition 3.2 and the definition of \( Z_q^g, U_1, M_2 \) that
\begin{equation}
|Z_q^g(i)| \leq M_2, \ i = 0, \ldots, q, \ q = 1, 2, \ldots.
\end{equation}
There exists a subsequence \( \{Z_{q_j}^g\}_{j=1}^\infty \) such that for any integer \( i \geq 0 \) there exists
\begin{equation}
z_q^g = \lim_{j \to \infty} Z_{q_j}^g(i).
\end{equation}

By Corollary 2.1 there exists an a.c. function \( Z^g : [0, \infty) \to K \) such that for each integer \( i \geq 0 \)
\begin{equation}
Z^g(i) = z_q^g, \ I^g(i, i + 1, Z^g) = U^g(i, i + 1, z_q^g, z_q^g).
\end{equation}
It follows from (4.9), (4.10) and (4.4) that
\begin{equation}
I^g(i, i + 1, Z_q^g) < Q_0, \ i = 0, \ldots, q - 1, \ q = 1, 2, \ldots.
\end{equation}
(4.10), (4.11), (4.12) and (4.4) imply that
\begin{equation}
I^g(i, i + 1, Z^g) < Q_0, \ i = 0, 1, \ldots.
\end{equation}
By (4.13), (4.14) and the definition of \( Q_1 \) (see (4.5), (4.6))
\begin{equation}
|Z_q^g(t)| \leq Q_1, \ t \in [0, q], \ q = 1, 2, \ldots, \ |Z^g(t)| \leq Q_1, \ t \in [0, \infty).
\end{equation}
Therefore for each \( g \in U \) and each \( z \in K \) satisfying \( |z| \leq M \) we define a.c. functions \( Z_q^g : [0, q] \to K, q = 1, 2, \ldots \) and \( Z^g : [0, \infty) \to K \) satisfying
\begin{equation}
(4.9)-(4.15).
\end{equation}
Lemma 4.1. Let $g \in U$, $z \in K$, $|z| \leq M$. Then for each pair of integers $q_1, q_2$ satisfying $0 \leq q_1 < q_2$ and each sequence $\{y_i\}_{i=q_1}^{q_2} \subset K$ satisfying $|y_{q_1}| \leq M_1$ the following relation holds:

$$(4.16) \quad \sum_{i=q_1}^{q_2-1} [U^g(i, i + 1, z_i^g, z_{i+1}^g) - U^g(i, i + 1, y_i, y_{i+1})] \leq 4 + 4Q_2.$$ 

Proof. Assume that integers $q_1, q_2$ satisfy $0 \leq q_1 < q_2$ and a sequence $\{y_i\}_{i=q_1}^{q_2} \subset K$ satisfies $|y_{q_1}| \leq M_1$. We will show that (4.16) holds.

Let us assume the converse. Then

$$(4.17) \quad \sum_{i=q_1}^{q_2-1} [U^g(i, i + 1, z_i^g, z_{i+1}^g) - U^g(i, i + 1, y_i, y_{i+1})] > 4 + 4Q_2.$$ 

By Corollaries 2.1, 2.2 we may assume without loss of generality that

$$\sum_{i=q_1}^{q_2-1} [U^g(i, i + 1, y_i, y_{i+1}) - U^g(i, i + 1, \bar{y}_i, \bar{y}_{i+1})] \leq 0$$

for each sequence $\{\bar{y}_i\}_{i=q_1}^{q_2} \subset K$ satisfying $\bar{y}_{q_1} = y_{q_1}$. It follows from (4.3), (4.5) that

$$(4.18) \quad |y_i| \leq M_2 < Q_1, \ i = q_1, \ldots q_2.$$ 

By Proposition 2.5, (4.9), (4.11) and (4.13) for any integer $i \geq 0$

$$U^g(i, i + 1, z_i^g, z_{i+1}^g) \leq \liminf_{j \to \infty} U^g(i, i + 1, Z_{q_j}^g(i), Z_{q_j}^g(i + 1)).$$

Therefore there exists an integer $q > q_2 + 1$ such that

$$(4.19) \quad \sum_{i=q_1}^{q_2} [U^g(i, i + 1, z_i^g, z_{i+1}^g) - U^g(i, i + 1, Z_q^g(i), Z_q^g(i + 1))] \leq 1.$$ 

We define a sequence $\{h_i\}_{i=0}^{q} \subset K$ as follows

$$(4.20) \quad h_i = Z_q^g(i), \ i \in \{0, \ldots q_1\} \cup \{q_2 + 1, \ldots q\}, \ h_i = y_i, \ i = q_1 + 1, \ldots q_2.$$ 

It follows from (4.20), (4.9), Corollary 2.1, (4.19) and (4.17) that

$$0 \geq \sum_{i=0}^{q-1} [U^g(i, i + 1, Z_q^g(i), Z_q^g(i + 1)) - U^g(i, i + 1, h_i, h_{i+1})].$$
\[\sum_{i=q_1}^{q_2} \left[ U^g(i, i + 1, Z^g_q(i), Z^g_q(i + 1)) - U^g(i, i + 1, h_i, h_{i+1}) \right] \]

\[= \sum_{i=q_1}^{q_2} \left[ U^g(i, i + 1, Z^g_q(i), Z^g_q(i + 1)) - U^g(i, i + 1, z^g_i, z^g_{i+1}) \right] \]

\[+ \sum_{i=q_1}^{q_2} U^g(i, i + 1, z^g_i, z^g_{i+1}) - \sum_{i=q_1}^{q_2-1} U^g(i, i + 1, y_i, y_{i+1}) + U^g(q_1, q_1+1, y_{q_1}, y_{q_1+1}) \]

\[-U^g(q_1, q_1 + 1, h_{q_1}, h_{q_1+1}) - U^g(q_2, q_2 + 1, h_{q_2}, h_{q_2+1}) \geq 3 + 4Q_2 \]

\[+ U^g(q_2, q_2 + 1, z^g_{q_2}, z^g_{q_2+1}) + U^g(q_1, q_1 + 1, y_{q_1}, y_{q_1+1}) \]

\[-U^g(q_1, q_1 + 1, h_{q_1}, h_{q_1+1}) - U^g(q_2, q_2 + 1, h_{q_2}, h_{q_2+1}). \]

Together with (4.20), (4.18), (4.10), (4.11), (4.5) and (4.7) this relation implies that

\[0 \geq 3 + 4Q + U^g(q_2, q_2 + 1, z^g_{q_2}, z^g_{q_2+1}) + U^g(q_1, q_1 + 1, y_{q_1}, y_{q_1+1}) \]

\[-U^g(q_1, q_1 + 1, Z^g_q(q_1), y_{q_1+1}) - U^g(q_2, q_2 + 1, y_{q_2}, Z^g_q(q_2+1)) \geq 3 + 4Q_2 - 4Q_2. \]

The obtained contradiction proves the lemma.

**Lemma 4.2.** Let \( g \in U, z \in K, |z| \leq M, \) an integer \( q \geq 0, T \in (q, \infty) \) and let \( x : [q, T] \to K \) be an a.c. function satisfying \( |x(q)| \leq M_1. \) Then

\[(4.21) \quad I^g(q, T, Z^g) \leq I^g(q, T, x) + 4 + 4Q_2 + Q_0 + 2a\]

(recall \( a \) in Assumption (Aiii)).

**Proof.** There exists an integer \( q_1 \geq q \) such that \( q_1 < T \leq q_1 + 1. \) It follows from Lemma 4.1 and (4.12) that

\[(4.22) \quad I^g(q, q_1, Z^g) \leq I^g(q, q_1, x) + 4 + 4Q_2.\]

By Assumption (Aiii) and (4.14)

\[(4.23) \quad I^g(q_1, T, x) \geq -a, \quad I^g(q_1, T, Z^g) \leq Q_0 + a.\]

(4.22) and (4.23) imply (4.21). The lemma is proved.
Lemma 4.3. Let \( g \in U \), \( z \in K \), \( |z| \leq M \), \( 0 \leq T_1 < T_2 \) and let \( x : [T_1, T_2] \to K \) be an a.c. function satisfying \( |x(T_1)| \leq M_1 \). Then

\[
I^g(T_1, T_2, Z^g) \leq I^g(T_1, T_2, x) + 4 + 4Q_2 + Q_0 + Q_3 + 3a. \tag{4.24}
\]

Proof. There exists an integer \( q \geq 0 \) such that \( q \leq T_1 < q + 1 \). Set

\[
x_1(t) = x(T_1), \ t \in [q, T_1], \ x_1(t) = x(t), \ t \in [T_1, T_2]. \tag{4.25}
\]

By Lemma 4.2

\[
I^g(q, T_2, Z^g) \leq I^g(q, T_2, x_1) + 4 + 4Q_2 + Q_0 + 2a. \tag{4.26}
\]

By Assumption (Aiii) and (4.26)

\[
I^g(T_1, T_2, Z^g) = I^g(q, T_2, Z^g) - I^g(q, T_1, Z^g) \leq I^g(q, T_2, Z^g) + a \leq I^g(q, T_2, x_1) + 4 + 4Q_2 + Q_0 + 3a. \tag{4.27}
\]

It follows from (4.25) and (4.8) that \( |I^g(q, T_1, x_1)| \leq Q_3 \). (4.24) now follows from this relation and Lemma 4.1. The lemma is proved. \( \blacksquare \)

Lemma 4.4. Let \( g \in U \), \( z \in K \), \( |z| \leq M \), \( \{y_i\}_{i=0}^\infty \subset K \),

\[
\limsup_{i \to \infty} |y_i| > M_2. \tag{4.28}
\]

Then

\[
\sum_{i=0}^{N-1} [U^g(i, i + 1, y_i, y_{i+1}) - U^g(i, i + 1, z_i^g, z_{i+1}^g)] \to \infty \text{ as } N \to \infty. \tag{4.29}
\]

Proof. There are two cases:

a) \( \liminf_{i \to \infty} |y_i| > 2^{-1}M_1 \);  b) \( \liminf_{i \to \infty} |y_i| \leq 2^{-1}M_1 \).

Consider the case a). Set \( h_i = \tilde{z} \) for \( i = 0, 1, \ldots \). It follows from (4.1), (4.2) that

\[
U^g(i, i + 1, y_i, y_{i+1}) - U^g(i, i + 1, h_i, h_{i+1}) \geq M_0 + 1
\]

for all large \( i \). (4.29) now follows from this relation and Lemma 4.1.

Consider the case b). By (4.28) there exists a subsequence \( \{y_{i_k}\}_{k=1}^\infty \) such that

\[
0 < i_k, \ |y_{i_k}| < M_1, \ \sup\{|y_j| : j = i_k, \ldots, i_{k+1}\} > M_2, \ k = 1, 2, \ldots
\]
It follows from (4.3), (4.30) and Proposition 3.2 that for any integer \( k \geq 1 \) there exists a sequence \( \{h_j\}_{j=i_k}^{i_{k+1}-1} \subset K \) such that \( h_j = y_j, j \in \{i_k, i_{k+1}\} \),

\[
(4.31) \sum_{j=i_k}^{i_{k+1}-1} [U^g(j, j + 1, y_j, y_{j+1}) - U^g(j, j + 1, h_j, h_{j+1})] \geq 1.
\]

Fix an integer \( q \geq 4 \). By (4.30), Lemma 4.1 and (4.31) for an integer \( N > i_q \)

\[
\sum_{j=i_q}^{i_{q+1}-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, h_j, h_{j+1})] \leq 4 + 4Q_2,
\]

\[
\sum_{j=i_{q+1}}^{N-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, y_j, y_{j+1})] \leq 4 + 4Q_2,
\]

\[
\sum_{j=0}^{N-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, y_j, y_{j+1})]
\]

\[
= \sum_{j=0}^{i_{q+1}-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, y_j, y_{j+1})]
\]

\[
+ \sum_{j=i_{q+1}}^{i_q-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, h_j, h_{j+1})]
\]

\[
+ \sum_{j=i_q}^{i_{q+1}-1} [U^g(j, j + 1, h_j, h_{j+1}) - U^g(j, j + 1, y_j, y_{j+1})]
\]

\[
+ \sum_{j=i_q}^{N-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, y_j, y_{j+1})]
\]

\[
\leq \sum_{j=0}^{i_{q+1}-1} [U^g(j, j + 1, z^g_j, z^g_{j+1}) - U^g(j, j + 1, y_j, y_{j+1})] + 2(4 + 4Q_2) - (q-1).
\]

This completes the proof of the lemma. \( \blacksquare \)

**Lemma 4.5.** Assume that \( g \in U, z \in K |z| \leq M \) and \( y : [0, \infty) \to K \) is an a.c. function which satisfies

\[
(4.32) \limsup_{t \to \infty} |y(t)| > Q_1.
\]

Then

\[
(4.33) I^g(0, T, y) - I^g(0, T, z^g) \to \infty \text{ as } T \to \infty.
\]
Proof. There are two cases: a) $\limsup_{i \to \infty} |y(i)| > M_2$; b) $\limsup_{i \to \infty} |y(i)| \leq M_2$ where $i$ is an integer. Consider the case a). It follows from Lemma 4.4, (4.12) that
\begin{equation}
I_g(0, q, y) - I_g(0, q, Z^g) \to \infty \text{ as an integer } q \to \infty.
\end{equation}
Let $T > 0$. There exists an integer $q(T) \geq 0$ such that
\begin{equation}
q(T) < T \leq q(T) + 1.
\end{equation}
By Assumption (Aiii) and (4.14)
\begin{equation}
I_g(0, q(T), T, y) \geq -a, I_g(q(T), T, Z^g) = I_g(q(T), q(T) + 1, Z^g)
\end{equation}
\begin{equation}
- I_g(T, q(T) + 1, Z^g) \leq Q_0 + a.
\end{equation}
Together with (4.34) these relations imply that
\begin{equation}
I_g(0, T, y) - I_g(0, T, Z^g) \geq I_g(0, q(T), y) - I_g(q(T), q(T) + 1, Z^g) \to \infty \text{ as } T \to \infty.
\end{equation}
Consider the case b). There exists an integer $i_0 \geq 2$ such that
\begin{equation}
|y(i)| \leq M_2 + 2^{-1} \text{ for all integers } i \geq i_0.
\end{equation}
By (4.37), (4.32), (4.4) and the definition of $Q_1$ (see (4.5))
\begin{equation}
\sum_{i=0}^{N} [I^g(i, i+1, y) - U^g(i, i+1, y(i), y(i + 1))] \to \infty \text{ as } N \to \infty.
\end{equation}
Define a sequence $\{d_i\}_{i=i_0}^{\infty} \subset K$ as follows
\begin{equation}
d_{i_0} = z, \quad d_i = y(i) \quad \text{for all integers } i > i_0.
\end{equation}
By Lemma 4.1 and the definition of $\{d_i\}_{i=i_0}$ for any integer $N \geq i_0 + 1$
\begin{equation}
\sum_{i=i_0}^{N} [U^g(i, i+1, y(i), y(i + 1)) - U^g(i, i+1, z_1^g, z_{i+1}^g)] =
\end{equation}
\begin{equation}
\sum_{i=i_0}^{N} [U^g(i, i+1, d_i, d_{i+1}) - U^g(i, i+1, z_1^g, z_{i+1}^g)] + U^g(i_0, i_0 + 1, z_{i_0}^g, z_{i_0+1}^g)
\end{equation}
\begin{equation}
- U^g(i_0, i_0 + 1, z, y(i_0 + 1)) \geq -4 - 4Q_2 +
\end{equation}
\begin{equation}
U^g(i_0, i_0 + 1, z_{i_0}^g, z_{i_0+1}^g) - U^g(i_0, i_0 + 1, z, y(i_0 + 1)).
\end{equation}
Together with (4.28), (4.12) this implies that
\begin{equation}
\sum_{i=0}^{N} [I^g(i, i+1, y) - I^g(i, i+1, Z^g)] \to +\infty \text{ as } N \to \infty.
\end{equation}
Let $T > 0$. There exists an integer $q(T) \geq 0$ satisfying (4.35). Clearly (4.36) holds. (4.33) now follows from (4.36) and (4.39). The lemma is proved. \hfill \blacksquare
Lemma 4.6. Let \( g \in U, \ z \in K, \ |z| \leq M \) and let \( y : [0, \infty) \to K \) be an a.c. function. Then one of the relations below holds:

(i) \( I^g(0, T, y) - I^g(0, T, Z^g) \to \infty \) as \( T \to \infty \);
(ii) \( \sup\{|I^g(0, T, y) - I^g(0, T, Z^g)| : T \in (0, \infty)\} < \infty \).

**Proof.** By Lemma 4.5 we may assume that \( \limsup_{t \to \infty} |y(t)| \leq Q_1 \). There exists an integer \( i_0 > 0 \) such that

\[
|y(t)| \leq Q_1 + 2^{-1}, \ t \in [i_0, \infty).
\]

Fix an integer \( i > i_0 \). By Corollary 2.1 there exists an a.c. function \( \bar{y} : [i - 1, \infty) \to K \) such that

\[
\bar{y}(i - 1) = z, \ \bar{y}(t) = y(t), \ t \in [i, \infty), \ I^g(i - 1, i, \bar{y}) = U^g(i - 1, i, z, y(i)).
\]

(4.7), (4.41), (4.40), (4.5) imply that \( |U^g(i - 1, i, z, y(i))| \leq Q_2 \). It follows from this relation, (4.41), Lemma 4.2 and Assumption (Aiii) that for each \( T > i \)

\[
I^g(i, T, y) - I^g(i, T, Z^g) = I^g(i - 1, T, \bar{y}) - I^g(i - 1, T, Z^g)
\]

\[
- I^g(i - 1, i, \bar{y}) + I^g(i - 1, i, Z^g) \geq -4 - 4Q_2 - Q_0 - 2a
\]

\[
- I^g(i - 1, i, \bar{y}) + I^g(i - 1, i, Z^g) \geq -4 - 5Q_2 - Q_0 - 3a.
\]

(4.42) holds for each integer \( i > i_0 \) and each \( T > i \).

Let \( S > i_0 + 1, \ T > S + 1 \). There exists an integer \( i > i_0 + 1 \) such that \( i - 1 \leq S < i \). Clearly (4.42) holds. By Assumption (Aiii) and (4.14)

\[
I^g(S, i, y) \geq -a, \ I^g(S, i, Z^g) = I^g(i - 1, i, Z^g) - I^g(i - 1, S, Z^g) \leq Q_0 + a.
\]

Together with (4.42) this implies that

\[
I^g(S, T, y) - I^g(S, T, Z^g) = I^g(i, T, y) - I^g(i, T, Z^g) + I^g(S, i, y) - I^g(S, i, Z^g)
\]

\[
\geq -4 - 5Q_2 - 2Q_0 - 5a.
\]

We established (4.43) for each \( S > i_0 + 1 \) and each \( T > S + 1 \).

Assume that (ii) does not hold. It follows from (4.14), Assumption (Aiii) and (4.43) which holds for each \( S > i_0 + 1, T > S + 1 \) that

\[
\inf\{|I^g(0, T, y) - I^g(0, T, Z^g) : T \in (0, \infty)\} > -\infty.
\]

Therefore \( \sup\{|I^g(0, T, y) - I^g(0, T, Z^g) : T \in (0, \infty)\} = \infty \). By Assumption (Aiii) and (4.14) \( \sup\{|I^g(0, i, y) - I^g(0, i, Z^g) : i = 1, 2, \ldots\} = \infty \). Together with (4.43) which holds for each \( S > i_0 + 1, T > S + 1 \) this implies (i). The lemma is proved. \( \blacksquare \)
Lemma 4.7. Assume that $K = R^n$, $g \in U$, $z \in K$, $|z| \leq M$, $0 \leq T_1 < T_2$.

Then

$$I^g(T_1, T_2, Z^g) = U^g(T_1, T_2, Z^g(T_1), Z^g(T_2)).$$

Proof. Let us assume the converse. Fix a number

$$\epsilon \in (0, 8^{-1}[I^g(T_1, T_2, Z^g) - U^g(T_1, T_2, Z^g(T_1), Z^g(T_2)))]$$

and an integer $q_0 > T_2 + 5$. By Corollary 2.1 there exists an a.c. function

$$y : [T_1, T_2] \to K$$

such that

$$y(T_i) = Z^g(T_i), \ i = 1, 2, \ I^g(T_1, T_2, y) = U^g(T_1, T_2, Z^g(T_1), Z^g(T_2)).$$

It follows from (4.10), (4.11), (4.12) and Proposition 2.7 that there exists an integer $k > 2q_0 + 4$ for which

$$U^g(q_0, q_0 + 1, Z^g(q_0), Z^g_k(q_0 + 1)) -$$

$$|U^g(q_0, q_0 + 1, Z^g(q_0), Z^g_k(q_0 + 1)) - U^g(q_0, q_0 + 1, Z^g_k(q_0 + 1))| \leq (2q_0 + 1)^{-1}\epsilon, \ i = 0, \ldots, 2q_0 + 1,$$

(4.46)

$$|U^g(q_0, q_0 + 1, Z^g(q_0), Z^g_k(q_0 + 1)) -$$

$$U^g(q_0, q_0 + 1, Z^g_k(q_0), Z^g_k(q_0 + 1))| \leq (2q_0 + 1)^{-1}\epsilon.$$ (4.47)

By Corollary 2.1 and (4.45) there exists an a.c. function $x : [0, k] \to K$ such that

$$x(t) = Z^g(t), \ t \in [0, T_1] \cup [T_2, q_0], \ x(t) = y(t), \ t \in [T_1, T_2],$$

$$x(t) = Z^g_k(t), \ t \in [q_0 + 1, k], \ I^g(q_0, q_0 + 1, x) = U^g(q_0, q_0 + 1, x(q_0), x(q_0 + 1)).$$

It follows from (4.48), (4.9) that

$$I^g(0, k, x) \geq I^g(0, k, Z^g_k).$$

By (4.48), (4.9), (4.12), (4.46), (4.47) and (4.44)

$$I^g(0, k, x) - I^g(0, k, Z^g_k) = I^g(0, q_0 + 1, x) - I^g(0, q_0 + 1, Z^g_k) =$$

$$-I^g(q_0, q_0 + 1, Z^g_k) \leq I^g(T_1, T_2, y) - I^g(T_1, T_2, Z^g)$$

$$+ \sum_{i=0}^{q_0-1} [U^g(i, i + 1, Z^g(i), Z^g(i + 1)) - U^g(i, i + 1, Z^g_k(i), Z^g_k(i + 1))]
+ U^g(q_0, q_0 + 1, Z^g(q_0), Z^g_k(q_0 + 1)) - U^g(q_0, q_0 + 1, Z^g_k(q_0), Z^g_k(q_0 + 1)) \leq$$

$$U^g(q_0, q_0 + 1, Z^g(q_0), Z^g_k(q_0 + 1)) - U^g(q_0, q_0 + 1, Z^g_k(q_0), Z^g_k(q_0 + 1)) \leq$$
\[ I^g(T_1, T_2, y) - I^g(T_1, T_2, Z^g) + \epsilon. \]

It follows from this relation, (4.44), (4.45) that
\[ I^g(0, k, x) - I^g(0, k, Z^g_k) \leq I^g(T_1, T_2, y) - I^g(T_1, T_2, Z^g) + \epsilon < -\epsilon. \]

This is contradictory to (4.49). The obtained contradiction proves the lemma.

\textit{Proof of Theorem 1.1.} At the beginning of Section 4 for each \( f \in M \) and each \( M > 2|\bar{z}| \) we constructed a neighborhood \( U \) of \( f \) in \( M \) and for each \( g \in U \) and each \( z \in K \) satisfying \(|z| \leq M\) we defined a.c. functions \( Z^g : [0, \infty) \to K, Z^g_q : [0, q] \to K, q = 1, 2, \ldots \) satisfying (4.9)-(4.15). Clearly an a.c. function \( Z^f : [0, \infty) \to K \) was defined for every \( f \in M \) and every \( z \in K \).

By Lemmas 4.5, 4.6 for each \( f \in M \) and each \( z \in K \) the function \( Z^f \) is (\( f \))-good and Assertion 1 of Theorem 1.1 holds.

Assertion 2 of Theorem 1.1 follows from (4.15) which holds for every \( g \in U \) (\( U \) is a neighborhood of \( f \) in \( M \)) and each \( z \in K \) satisfying \(|z| \leq M\).

Assertion 3 of Theorem 1.1 follows from Lemma 4.3. Lemma 4.7 implies Assertion 4 of Theorem 1.1. Theorem 1.1 is proved.

Theorem 1.2 follows from Lemma 4.5.

\textit{Proof of Theorem 1.3.} Fix \( \bar{z} \in K \). By Proposition 2.6 there exists a neighborhood \( U_0 \) of \( f \) in \( M \) and a number
\[ M_0 \geq \sup\{|U^g(T_1, T_2, y, z)| : g \in U_0, T_1 \in [0, \infty), T_2 \in [T_1 + c, T_1 + 2c + 2], y, z \in K, |y|, |z| \leq 2|\bar{z}| + 1\}. \]

By Proposition 2.3 we may assume without loss of generality that
\[ \inf\{|U^g(T_1, T_2, y, z)| : g \in M, T_1 \in [0, \infty), T_2 \in [T_1 + c, T_1 + 2c + 2], y, z \in K, |y| + |z| \geq M_1\} > 2M_0 + 1. \]

There exists a neighborhood \( U_1 \) of \( f \) in \( M \) and a number \( S_1 \) such that
\[ U_1 \subset U_0, S_1 > M_1 \text{ and Proposition 3.2 holds with} \]
\[ M_3 = M_2 + 2, M_4 = S_1, V = U_1, c_1 = c, c_2 = 2c + 2. \]

By Proposition 2.6 there exist a neighborhood \( U \) of \( f \) in \( M \) and a number \( M_3 > 0 \) such that
\[ U \subset U_1, M_3 > \sup\{|U^g(T_1, T_2, y, z)| : g \in U, T_1 \in [0, \infty), T_2 \in [T_1 + c, T_1 + 2c + 2], y, z \in K, |y|, |z| \leq S_1\}. \]
By Proposition 2.3 there exist $S > S_1 + 1$ such that $|v(t)| \leq S$, $t \in [T_1, T_2]$ for each $g \in \mathfrak{M}$, each $T_1 \in [0, \infty)$, $T_2 \in [T_1 + c, T_1 + 2c + 2]$ and each a.c. function $v : [T_1, T_2] \to K$ satisfying $I^g(T_1, T_2, v) \leq 2M_3 + 2M_2 + 2$.

Assume that $g \in U$, $T_1 \in [0, \infty)$, $T_2 \geq c + T_1$. We will show that property (i) holds.

Let $x, y \in K$, $|x|, |y| \leq M_1$ and let $v : [T_1, T_2] \to K$ be an a.c. function which satisfies

(4.54) \[ v(T_1) = x, \quad v(T_2) = y, \quad I^g(T_1, T_2, v) \leq U^g(T_1, T_2, x, y) + M_2. \]

There is a natural number $p$ such that $pc \leq T_2 - T_1 < (p+1)c$. Set $T = p^{-1}(T_2 - T_1)$. Clearly $T \in [c, 2c]$. By (4.54) and Corollary 2.1

\[ \sum_{i=0}^{p-1} [U^g(T_1 + iT, T_1 + (i+1)T, v(T_1 + iT), v(T_1 + (i+1)T))] - U^g(T_1 + iT, T_1 + (i+1)T, y_i, y_{i+1})] \leq M_2 \]

for each sequence $\{y_i\}_{i=0}^p \subset K$ satisfying $y_0 = v(T_1)$, $y_p = v(T_2)$. It follows from this, (4.52), (4.54) and Proposition 3.2 that

\[ |v(T_1 + iT)| \leq S_1, \quad i = 0, \ldots, p. \]

By this relation and (4.54), (4.53) for $i = 0, \ldots, p - 1$

\[ I^g(T_1 + iT, T_1 + (i+1)T, v) \leq U^g(T_1 + iT, T_1 + (i+1)T, v(T_1 + iT), v(T_1 + (i+1)T)) + M_2 < M_3 + M_2. \]

It follows from this relation and the definition of $S$ that

\[ |v(t)| \leq S, \quad t \in [T_1, T_2]. \]

Therefore property (i) holds. Analogously to this we can show that property (ii) holds. The theorem is proved.

Special Issue on
Boundary Value Problems on Time Scales

Call for Papers

The study of dynamic equations on a time scale goes back to its founder Stefan Hilger (1988), and is a new area of still fairly theoretical exploration in mathematics. Motivating the subject is the notion that dynamic equations on time scales can build bridges between continuous and discrete mathematics; moreover, it often reveals the reasons for the discrepancies between two theories.

In recent years, the study of dynamic equations has led to several important applications, for example, in the study of insect population models, neural network, heat transfer, and epidemic models. This special issue will contain new researches and survey articles on Boundary Value Problems on Time Scales. In particular, it will focus on the following topics:

- Existence, uniqueness, and multiplicity of solutions
- Comparison principles
- Variational methods
- Mathematical models
- Biological and medical applications
- Numerical and simulation applications

Before submission authors should carefully read over the journal’s Author Guidelines, which are located at http://www.hindawi.com/journals/ade/guidelines.html. Authors should follow the Advances in Difference Equations manuscript format described at the journal site http://www.hindawi.com/journals/ade/. Articles published in this Special Issue shall be subject to a reduced Article Processing Charge of €200 per article. Prospective authors should submit an electronic copy of their complete manuscript through the journal Manuscript Tracking System at http://mts.hindawi.com/ according to the following timetable:

<table>
<thead>
